Lecture 5: Fundamentals of Machine Learning Pt. 2

INFO 1998: Introduction to Machine Learning

Tuning Models

Announcements

Web Scraping Workshop: April 10th 3-4PM

<u>Mid-Semester Check-in:</u> Mandatory check in, come stop by any one of our office hours from now until Lecture 7 and discuss your plans for your project. We're looking for Problem statements/hypotheses, a dataset, and some progress coding.

What We'll Cover

Last Time's Goal: identify what ML is and write ML code (to some extent)

This Time's Goal: how to tell if your ML model is useful

Agenda

- 1. Review
- 2. Measuring Accuracy
- 3. Bias-Variance trade-off
- 4. Feature Selection
- 5. Other Types of machine learning

Review: Defining ML

We want to predict the future

- Take some known input and output
- Learn the data's pattern and come up with a way to, given a future input, predict the corresponding output

Now: *how* do we learn the data's pattern?

Review: Model

- Something you use to predict outputs
- The Linear Regression Algorithm produces Linear Regression Models
- "Model training" = learn a relationship/program
- "Model validation" = see if the learned relationship is accurate on other data

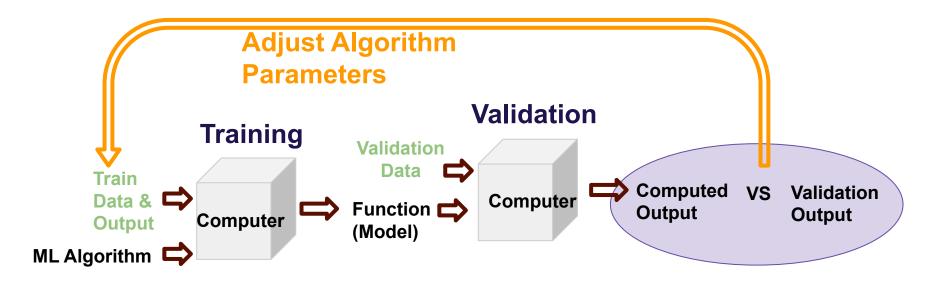

Measuring Bias / Loss (training accuracy)

- 1. Split data (lecture 7)
- 2. Assess model accuracy (today)
- 3. Adjust Model (a bit today)

Loss, Cost, and Score Functions

Loss Function

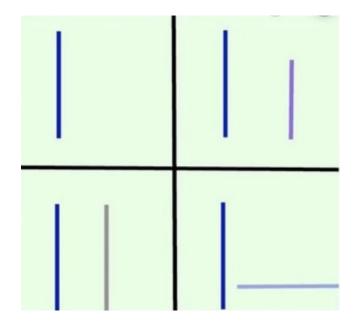

Penalty for missing a single data point

Cost Function

- Indicates how bad the whole model is
- Applies loss function to each point, then combines that into a single number
 - ex: average of (loss from each point)

Score Function

 A more interpretable version of the cost function (how well we did)

Linear Regression Loss Formula: Euclidean Distance

loss
$$(x, y^*) = (h(x) - y^*)^2$$

Two things to note about this loss function:

- Positives and negatives won't cancel
- Large errors are penalized to a power of 2 more
- Cost Function average of the loss function over all the points

Solution: Compare to Baseline

- When determining accuracy, usually want to compare our model to a baseline
 - For regression, one baseline model is the model that predicts the average of the target value for every point
 - For our purposes: don't worry about the baseline model, just have a set of baseline predictions

Cost -> Accuracy Score

sklearn's score function is:

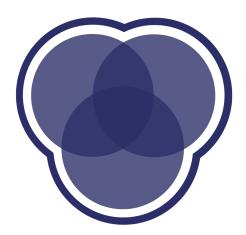

1 - ([Cost of model] / [Cost of baseline])

- 1 is very, very good
- 0 means you were as bad as the baseline
- <0 means either your baseline predictions were accurate, or you really, really messed up

Demo

Overfitting and Underfitting

(what makes a model good?)

Model Goals

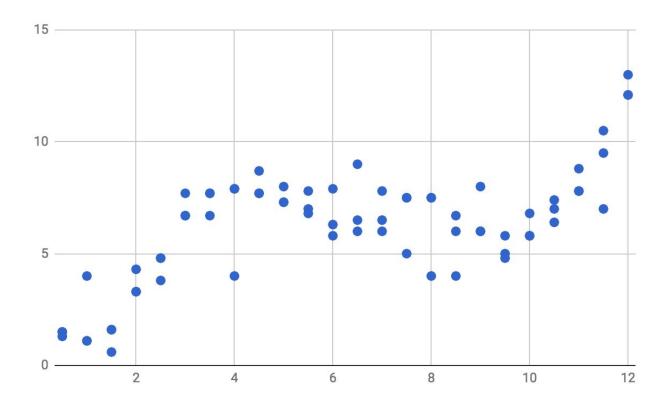

When training a model, we want our model to:

- Capture the trends of the training data
- Generalize well to other samples of the population
- Be moderately interpretable

The first two are especially difficult to do simultaneously!
The more sensitive the model, the less generalizable and vice versa.

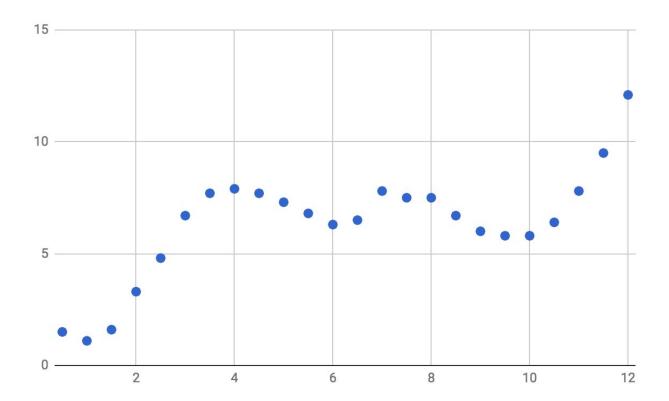

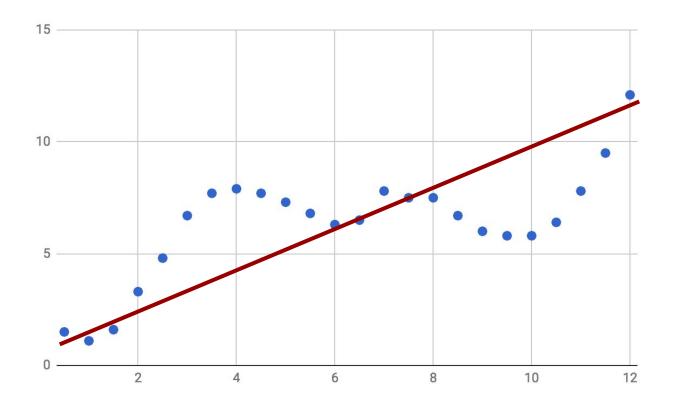

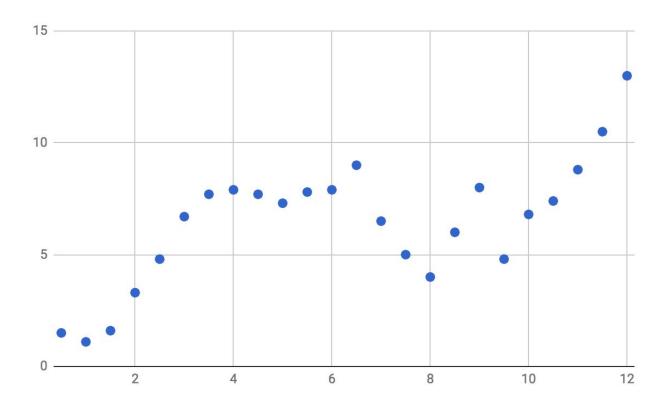

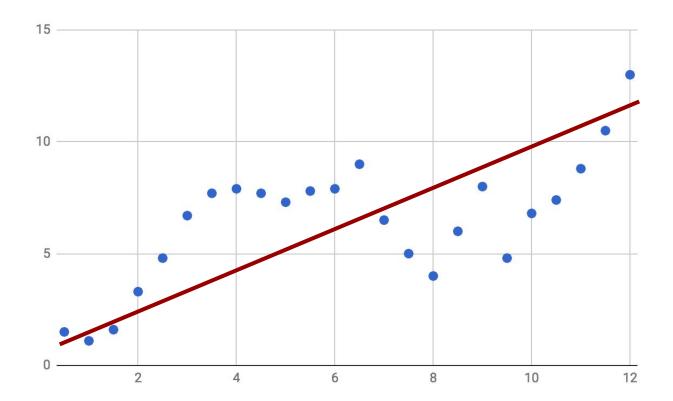

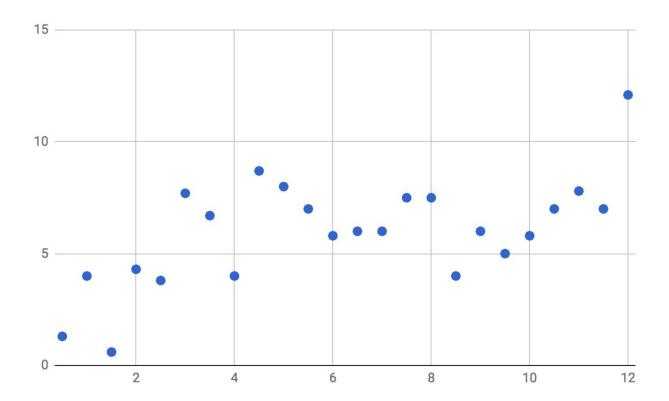

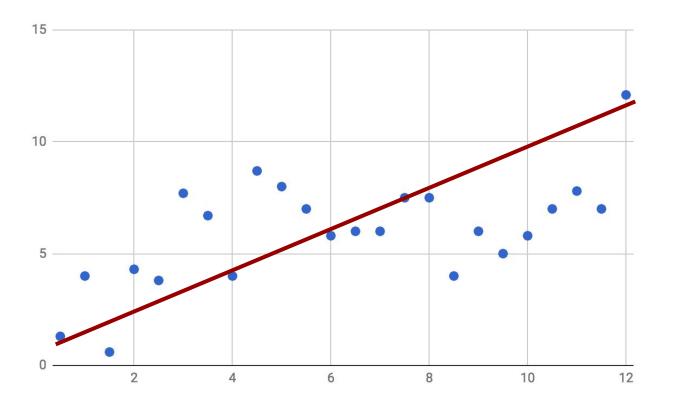

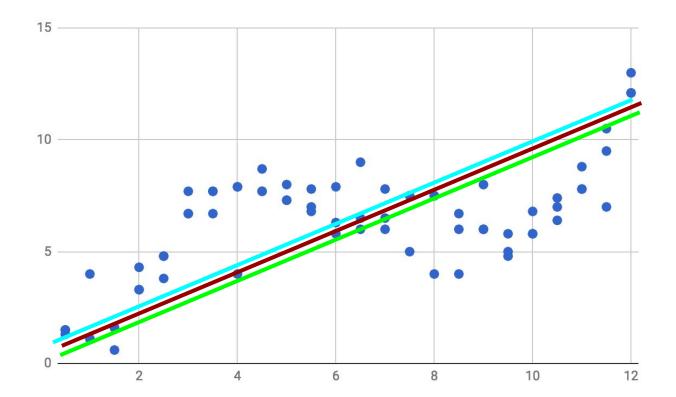

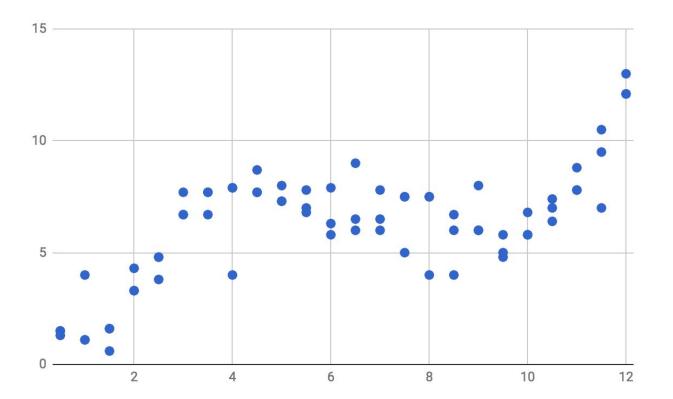

Underfitting: at least the models are consistent...

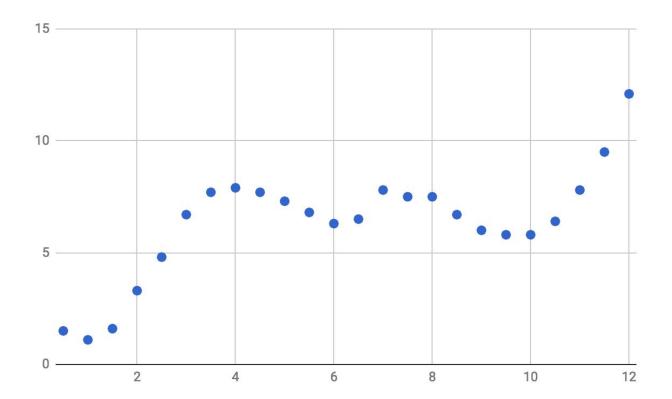

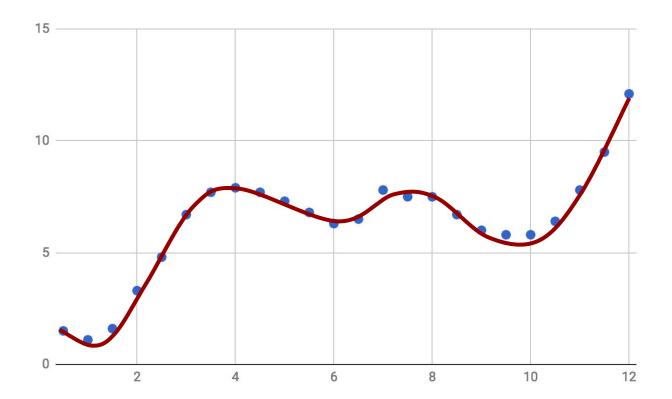

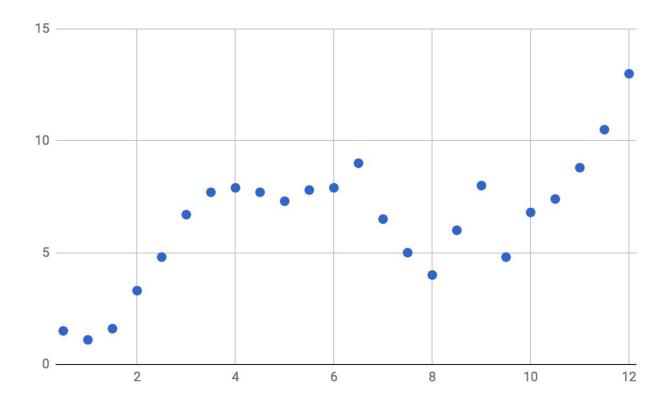

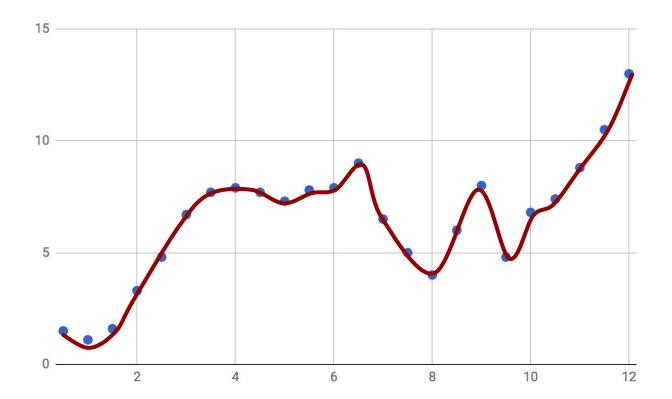

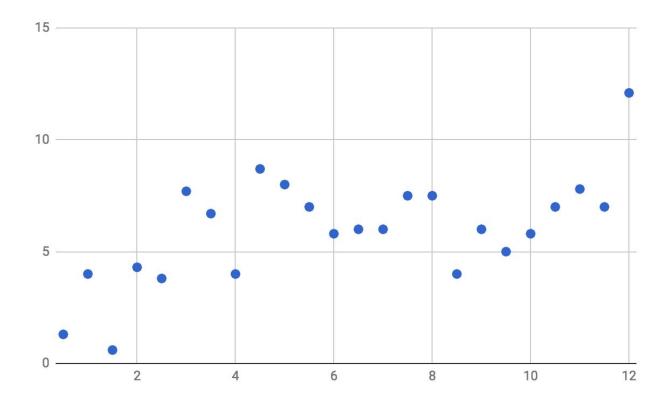

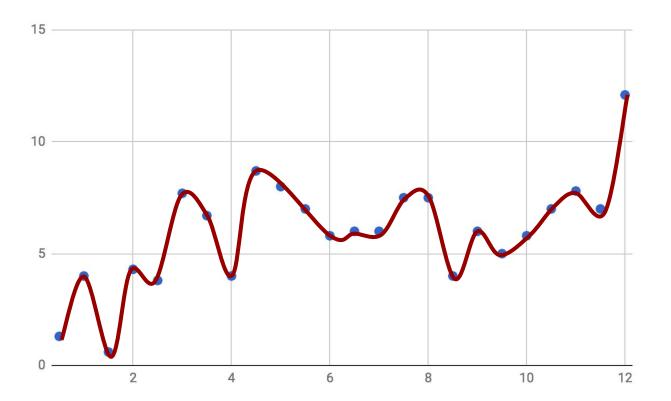

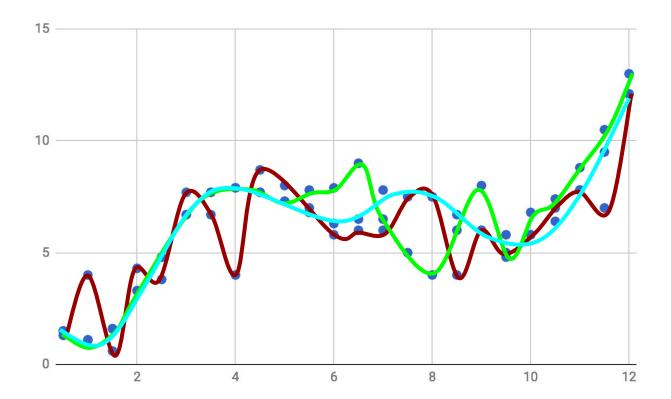

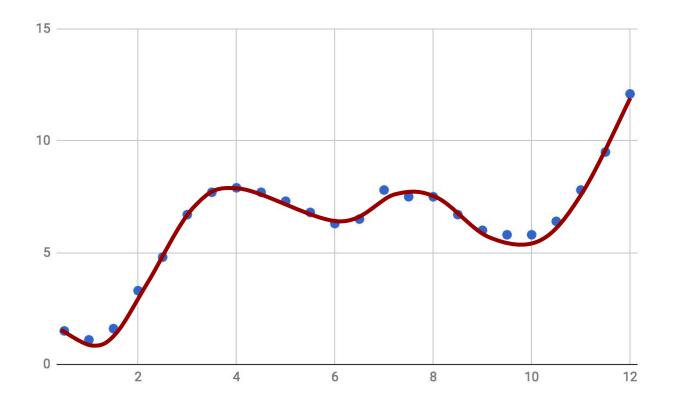

Overfitting: Inconsistent Models!

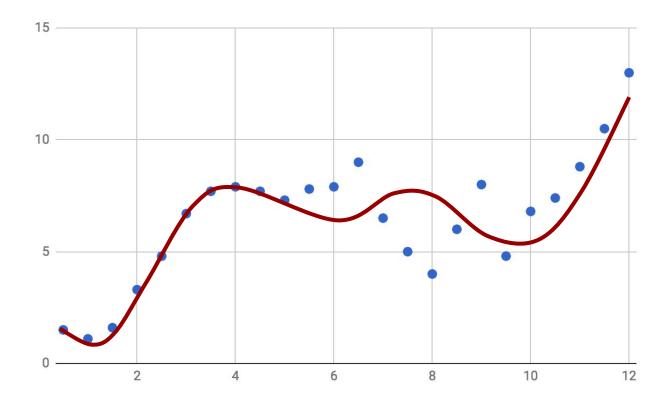

Overfitting: Results from training with high sensitivity

Overfitting: doesn't generalize well!

Definitions

Bias

- A measure of underfitting

Variance

- A measure of overfitting

Either alone is hard to interpret, but together they are helpful http://www.r2d3.us/visual-intro-to-machine-learning-part-2/

Balancing Bias and Variance

$$\mathrm{E}\!\left[\left(y-\hat{f}\left(x
ight)
ight)^{2}
ight]=\mathrm{Bias}\!\left[\hat{f}\left(x
ight)
ight]^{2}+\mathrm{Var}\!\left[\hat{f}\left(x
ight)
ight]+\sigma^{2}$$

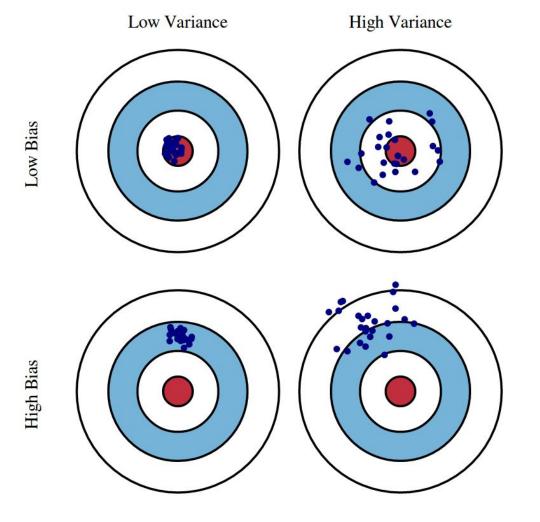

$$\operatorname{Bias}igl[\hat{f}\left(x
ight)igr] = \operatorname{E}igl[\hat{f}\left(x
ight) - f(x)igr]$$

$$\operatorname{Var} \left[\hat{f} \left(x
ight)
ight] = \operatorname{E} \left[\hat{f} \left(x
ight)^2
ight] - \operatorname{E} \left[\hat{f} \left(x
ight)
ight]^2$$

Error = $(expected loss of accuracy)^2 + inconsistency of model + irreducible error$

What does this mean intuitively?

Bias

- Bad
- Results from incorrect assumptions in the learning algorithm

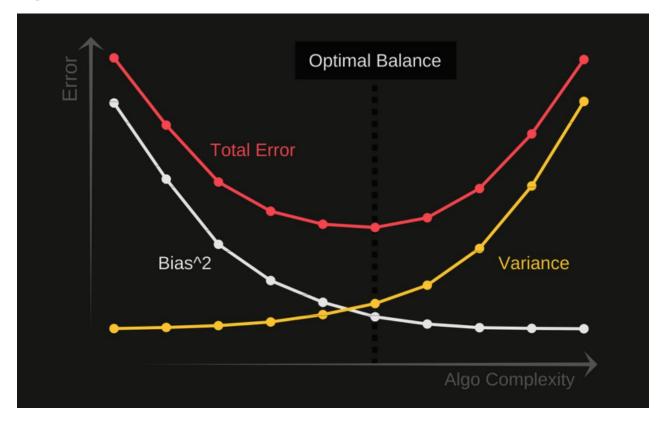

Variance

- Bad
- Results from sensitivity to fluctuations in the data

Balancing Bias and Variance

Feature Selection (adjusting models)

 Goal: Find subset of features that gives a good enough model, in a reasonable amount of time.

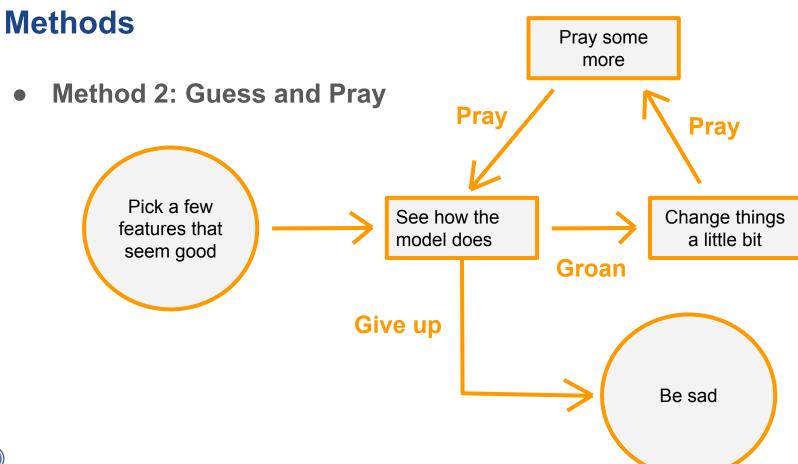

- Goal: Find subset of features that gives a good enough model, in a reasonable amount of time.
- Method 1: Best Subset
 - Test all subsets for best one
 - Benefits:
 - **Best** subset out of current features
 - Drawbacks:
 - Slow
 - Even slower with feature engineering

- Goal: Find subset of features that gives a good enough model, in a reasonable amount of time.
- Method 2: Guess and Pray
 - Guess
 - Benefits:
 - **?**?
 - Drawbacks:
 - Time consuming for data scientist
 - Unreliable

- Goal: Find subset of features that gives a good enough model, in a reasonable amount of time.
- Method 3: Stepwise
 - Pick a few features, then programmatically add/remove features using statistics
 - Benefits:
 - Complexity and runtime are adjustable
 - Drawbacks:
 - Can do very badly if you're not careful
 - Requires more thinking

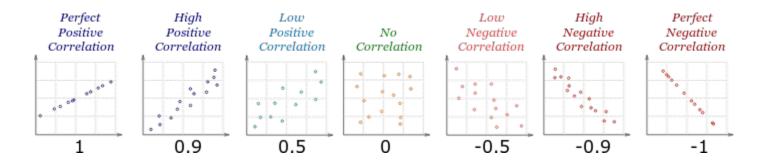

Correlation, r

The correlation between two variables describes to what extent changing one would change the other.

- Real-valued in [-1,1]
- A variable is always perfectly correlated with itself (correlation=1)

Important Case: Collinearity

Collinear: when two features have a correlation near -1 or 1

- If a feature is collinear with the target, then it's a good choice for linear regression
- If two features are collinear, they're *redundant*
 - Might as well not use one of them
 - Some models require/assume that no features used are collinear

Side Note: Scaling and Normalizing

- Some models require data to be centered
- Some models need features to be on the same scale

- A few ways of doing it
- Divide by max, minus min divide by max, minus mean divide by standard deviation.

Other Ways to Adjust your Model

- HyperParameters

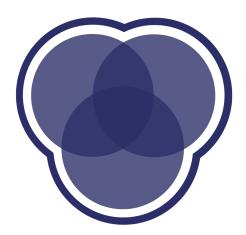

- Feature engineering

- Just changing to a different algorithm

Demo

Different Types of ML

(supervised & unsupervised) (classification & regression)

Supervised vs. Unsupervised

Supervised learning...

- Known target variable info
- Validation examples

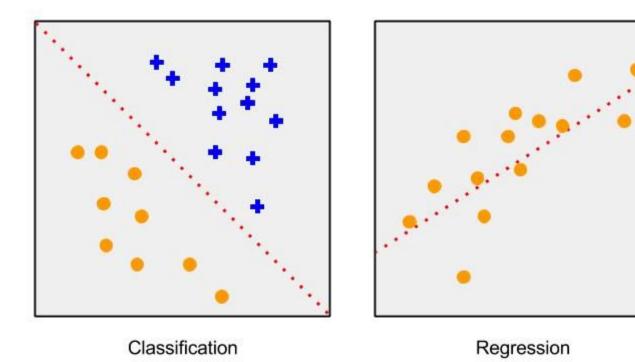

Unsupervised learning...

- Unknown target variables
- Difficult to validate

Classification vs. Regression

Other Classes of ML Algorithms (which we won't cover)

- What if you can't / don't want to see all your data at once?
- Maybe you only want to use a few pieces of your data (but don't have the time to manually select each piece of data...)

- A different approach, Trial & Error: The algorithm tries one thing, sees how that works, makes adjustments, tries again, etc.

Final Notes

Always remember both bias and variance!

Coming Up

- Assignment 5: Due at 4:30pm on April 7, 2021
- Next Lecture: Intro to Classification
- Last week to drop: April 5th
